Tidy format (murders data)

We say that a data table is in **tidy** format if each row represents one observation and columns represent the different variables available for each of these observations. For example, the following data is in tidy format:

```
data(murders)
head(murders)
```

```
##
           state abb region population total
## 1
         Alabama
                   AT.
                       South
                                  4779736
                                             135
## 2
          Alaska
                   AK
                         West
                                   710231
                                              19
## 3
         Arizona
                   AZ.
                         West
                                  6392017
                                             232
## 4
        Arkansas
                   AR.
                       South
                                  2915918
                                              93
                                 37253956
     California
                   C\Delta
                         West
                                            1257
## 6
       Colorado
                   CO
                         West.
                                  5029196
                                              65
```

Not tidy format (fertility)

country 1960 1961 1962

Germany 2.41 2.44 2.47

2 South Korea 6 16 5 99 5 79

##

1

The following dataset is organized, but not tidy. Why?

```
path <- system.file("extdata", package = "dslabs")</pre>
filename <- file.path(path, "fertility-two-countries-example.csv")</pre>
wide data <- read csv(filename)</pre>
## Rows: 2 Columns: 57
## -- Column specification -----
## Delimiter: "."
## chr (1): country
## dbl (56): 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, ...
##
## i Use `spec()` to retrieve the full column specification for this data.
## i Specify the column types or set `show_col_types = FALSE` to quiet this message.
select(wide_data, country, `1960`: 1962`) %>% as.data.frame()
```

Tidy format (fertility)

Here is how we would organize these data to be tidy:

```
data("gapminder")
tidy_data <- gapminder %>%
    filter(country %in% c("South Korea", "Germany") &
        !is.na(fertility)) %>%
    select(country, year, fertility)
head(tidy_data, 6)
```

```
##
        country year fertility
        Germany 1960
                           2.41
  2 South Korea 1960
                          6.16
## 3
        Germany 1961
                          2.44
## 4 South Korea 1961
                          5.99
## 5
        Germany 1962
                           2.47
  6 South Korea 1962
                           5.79
```

Tidy format

The same information is provided, but there are important differences in the format. For the **tidyverse** packages to be optimally used, data need to be reshaped into 'tidy' format. The advantage of working in tidy format allows the data analyst to focus on more important aspects of the analysis rather than the format of the data.

Tidy data wrangling

The **dplyr** package, which is part of the **tidyverse**, presents a basic grammar for wrangling tidy data:

- mutate(): add or modify existing columns
- select(): take a subset of the columns (variables)
- filter(): take a subset of the rows (observations)
- arrange(): sort the rows
- summarize(): aggregate data across rows

Note an important point: most dplyr functions (and most functions in the tidyverse) input a tibble and then output a modified tibble!

Mutate

The function **mutate** takes the data frame, the instructions for the new columns in next arguments, and returns a modified data frame. For example:

head(murders)

```
##
           state abb region population total
        Alabama
                  AT.
                       South
                                 4779736
                                            135
## 1
         Alaska
                  ΑK
                                  710231
                                             19
## 2
                        West.
## 3
        Arizona
                  A 7.
                        West.
                                 6392017
                                            232
##
       Arkansas
                   AR.
                                 2915918
                                             93
                       South
     California
                  CA
                        West.
                                37253956
                                           1257
##
  6
       Colorado
                   CO
                        West
                                 5029196
                                             65
```

Mutate

To add murder rates, we mutate as follows:

```
murdersRate <- mutate(murders,
  rate = total / population * 100000
)
head(murdersRate)</pre>
```

```
##
          state abb region population total
                                                 rate
                 AT.
## 1
        Alabama
                     South
                               4779736
                                         135 2.824424
## 2
         Alaska
                 ΑK
                      West
                                710231
                                          19 2.675186
## 3
        Arizona
                 AZ.
                      West
                               6392017
                                         232 3.629527
                               2915918
## 4
       Arkansas
                 AR.
                     South
                                          93 3 189390
                              37253956
                                        1257 3.374138
     California
                 CA
                      West
## 6
       Colorado
                 CO
                      West.
                               5029196
                                          65 1 292453
```

Filter

Now suppose that we want to filter the data table to only show the entries for which the murder rate is lower than 0.71. We do this as follows:

```
filter(murdersRate, rate <= 0.71)</pre>
```

##		state	abb	region	population	total	rate
##	1	Hawaii	ΗI	West	1360301	7	0.5145920
##	2	Iowa	IA	North Central	3046355	21	0.6893484
##	3	New Hampshire	NH	Northeast	1316470	5	0.3798036
##	4	North Dakota	ND	North Central	672591	4	0.5947151
##	5	Vermont	VT	Northeast	625741	2	0.3196211

Select

##

If we want to view just a few of our columns, we can use the following:

rate

```
murdersRate <- mutate(murders,
    rate = total / population * 100000
)
murdersRateSelect <- select(murdersRate, state, rate)
filter(murdersRateSelect, rate <= 0.71)</pre>
```

```
## 1 Hawaii 0.5145920
## 2 Iowa 0.6893484
## 3 New Hampshire 0.3798036
## 4 North Dakota 0.5947151
## 5 Vermont 0.3196211
```

state

Nesting functions

Instead of defining new objects along the way, we could do everything in one complex nested function:

```
## state rate

## State rate

## Handi O 51/50/20
```

1 Hawaii 0.5145920 ## 2 Iowa 0.6893484 ## 3 New Hampshire 0.3798036 ## 4 North Dakota 0.5947151 ## 5 Vermont 0.3196211

This is fairly concise but a little confusing. Is there a better way?

Pipes

In the previous example, we performed the following wrangling operations:

original data $\,\rightarrow\,$ mutate $\,\rightarrow\,$ select $\,\rightarrow\,$ filter

As with Unix, we can perform a series of operations in R by sending the results of one function to another using the **pipe operator**: %>%. As of R version 4.1.0, you can also use |>.

The pipe is a combination of characters that when used properly does two things: *It* shortens and simplifies the code and it makes the code intuitive to read.

Pipes

All the pipe does is provide **forward application** of an object to the first argument of a function. The pipe sends left side of the input to the function to the right of the pipe. For example, if we wanted to calculate

$$\log_2(\sqrt(16))$$

We could use:

```
## [1] 2
```

Since the pipe inputs to the first argument, we can define other arguments as follows:

Pipes (murders)

Completing the prior tibble operation using pipes:

```
murders %>%

mutate(rate = total / population * 100000) %>%

select(state, rate) %>%

filter(rate <= 0.71)

## state rate
## 1 Hawaji 0.5145920
```

Note that as you can see, the pipe operators (%>% or |>) are not specific to the tidyverse, in fact they come from the **magrittr** package (which is loaded by the tidyverse and dplyr libraries)

Arrange

We know about the **order** and **sort** functions, but for ordering entire tables, the **arrange** function is much more useful. For example, here we order the states murder rate:

```
murdersRate %>%
  arrange(rate) %>%
  head()
```

##		state	abb	region	${\tt population}$	total	rate
##	1	Vermont	VT	Northeast	625741	2	0.3196211
##	2	New Hampshire	NH	Northeast	1316470	5	0.3798036
##	3	Hawaii	ΗI	West	1360301	7	0.5145920
##	4	North Dakota	ND	North Central	672591	4	0.5947151
##	5	Iowa	IA	North Central	3046355	21	0.6893484
##	6	Idaho	ID	West	1567582	12	0.7655102

Arrange (descending order)

Note that the default behavior is to order in ascending order. The function **desc** transforms a vector so that it is in descending order. To sort the table in descending order, we can type:

```
murdersRate %>%
  arrange(desc(rate)) %>%
  head()
```

```
##
                     state abb
                                       region population total
                                                                      rate
     District of Columbia
                                        South
                                                   601723
                                                              99 16 452753
##
                 Louisiana
                                                  4533372
                                                             351
                                                                  7.742581
                                        South

                                                             321
                                                                  5.359892
##
                                                  5773552
                                                             293
                                                                  5.074866
                  Marvland
                            MD
                                        South
## 5
           South Carolina
                            SC
                                        South
                                                  4625364
                                                             207
                                                                  4.475323
##
  6
                  Delaware
                            DE
                                        South
                                                   897934
                                                              38
                                                                  4 231937
```

Nested sorting

If we are ordering by a column with ties, we can use a second (or third) column to break the tie. for example:

```
murdersRate %>%
  arrange(region, rate) %>%
  head()
```

```
##
                          region population total
             state abb
                                                         rate
           Vermont.
                    VT Northeast
                                      625741
                                                  2 0 3196211

```

Summarize

The **summarize** function computes summary statistics in an intuitive way. The 'heights' dataset includes heights and sex reported by students in an in-class survey.

```
data(heights)
heights %>%
  filter(sex == "Female") %>%
  summarize(
   avg = mean(height),
   std_dev = sd(height)
)
```

```
## avg std_dev
## 1 64.93942 3.760656
```

Group then summarize with 'group_by'

A common operation in data exploration is to first split data into groups and then compute summaries for each group. For example, we may want to compute the average and standard deviation for men's and women's heights separately. We can do the following

```
heights %>%
  group_by(sex) %>%
  summarize(
   average = mean(height),
   standard_deviation = sd(height)
)
```

```
## # A tibble: 2 x 3
## sex average standard_deviation
## <fct> <dbl> <dbl>
## 1 Female 64.9 3.76
## 2 Male 69.3 3.61
```

More on the tidyverse

As you learn more about the tidyverse you will learn a few more tidyverse operations, including the **inner_join**, **left_join**, **pull**, **dot**, and **do** functions, and the **tidyr** package.
